Stress fractures of the acromion and scapular spine are well-known complications following reverse total shoulder arthroplasty. However, these fractures in patients with massive rotator cuff tear or cuff tear arthropathy are extremely rare, and the pathogenesis, clinical features, diagnosis, and treatment of these fractures are poorly understood. We report a case of bilateral stress fracture of the posterior angle of the acromion in a patient with massive rotator cuff tear and discuss the pathogenesis, clinical manifestation, and treatment with a review of the literature.

**Keywords:** Scapula; Acromion; Fracture; Rotator cuff tear

CASE REPORT

An 80-year-old woman visited Keimyung University Dongsan Medical Center with severe pain and limited motion of the right shoulder for 2 weeks. There was no history of acute trauma. She was an orchard farmer with long-standing pain in both shoulders for 10 years. One year ago, she was diagnosed with irreparable MRCT on her right shoulder, and RTSA was recommended by a physician at the local clinic if her pain and disability worsened.

Physical examination of the right shoulder revealed overall tenderness on the superior and posterior area without swelling or redness. The active range of motion (ROM) was not able to be assessed due to severe pain. The t-score of bone mineral density was −4.9. Plain radiographs and computed tomography (CT) on the right shoulder revealed a slightly displaced fracture of the posterior
angle of the acromion and superior migration of the humeral head (Fig. 1). Magnetic resonance imaging revealed chronic MRCT involving the supraspinatus, infraspinatus, and subscapularis (Fig. 2). The torn supraspinatus and infraspinatus tendons were retracted at the level of the glenoid with moderate muscle atrophy and fatty infiltration.

Because the patient also had long-standing symptoms in the left shoulder, plain radiographs of the left shoulder were obtained and revealed nonunion of the posterior part of the acromion and superior migration of humeral head (Fig. 3). On physical examination of the left shoulder, there was no specific tenderness on the acromion and active ROM was 140° of forward flexion, 130° of abduction, 60° of external rotation at the side, and internal rotation of the third lumbar vertebra level. She vaguely remembered a history of sudden onset pain and limited motion in the left shoulder several years ago. The symptoms improved by conservative treatment from the local clinic. However, she didn’t remember the exact diagnosis of the left shoulder at that time.

Despite conservative treatment including immobilization and medication for 2 weeks after initial presentation, the patient complained of unbearable right shoulder pain, and ROM had not improved. Therefore, the patient opted for open reduction and internal fixation (ORIF) and provided consent. After induction of general anesthesia, the patient was placed in the 60° beach chair position. An incision was made along the scapular spine towards the lateral edge of the acromion. After soft tissue dissection, the trapezius and deltoid fascia were opened towards the spine, and the fracture site was exposed. After the fracture was reduced using reduction forceps, two cannulated screws were fixed in a direction perpendicular to the fracture line. Then, a lateral clavicle anatomical plate (Acumed, Hillsboro, OR, USA) was bent along the acromial bony contour and fixed.

After surgery, the patient experienced immediate pain relief and started passive ROM exercise 2 weeks later. Two years after surgery, plain radiographs revealed complete healing of the fracture (Fig. 4). The active ROM was 130° of forward flexion, 120° of abduction, 50° of external rotation at the side, and internal rotation of the second lumbar vertebra level. Her visual analogue scale for

pain, American Shoulder and Elbow Surgeons score, and Subjective Shoulder Value were 1, 82, and 70%, respectively.

**DISCUSSION**

Stress fractures of the acromion and scapular spine in patients with MRCT or CTA are extremely rare and poorly understood. To date, there have been 11 cases reported in five studies of stress fractures of the acromion and scapular spine in patients with CTA (Table 1) [5-9].

Previous studies proposed the mechanism of stress fracture according to fracture location [5,8,9]. Dennis et al. [5] reported acromial stress fractures caused by superior migration of the humeral head in patients with MRCT or CTA. Abnormal pressure from the humeral head on the acromion in patients with CTA leads to acromial thinning and subsequent fracture of the anterior or lateral acromion [8]. Meanwhile, the mechanism for stress fractures of the acromial base or scapular spine in patients with CTA may be different. Shindle et al. [9] reported that scapular spine stress fractures are the result of altered mechanics about the shoulder compensating for the lack of a rotator cuff. They reported two cases of scapular spine stress fracture due to an indirect mechanism of a bending moment created by the trapezius and deltoid [9]. In the present study, our case had bilateral stress fractures of the posterior angle of the acromion in patient with MRCT, not CTA. Although superior migration of both humeral heads was evident, the acromiohumeral interval was preserved to more than 5 mm. Therefore, the pathomechanism in our case may be consistent with that proposed by Shindle et al. [9].

Patients with CTA who experienced stress fractures of the acromion or scapular fractures had sudden onset shoulder pain without a history of trauma, although the pain occurred insidiously as well [5]. If these fractures are suspected from history taking and physical examination, plain radiographs (especially, the axillary lateral view) and CT are useful to confirm the diagnosis. It is important that plain radiographs of the unaffected shoulder be taken, because these fractures can be confused with os acromiale [5]. Stress fracture of the acromion or scapular spine should be considered in the differential diagnosis when patients with MRCT or CTA complain of sudden onset severe shoulder pain and limited motion without a history of trauma.

Previous studies reported that most acromial stress fractures were minimally displaced fractures and healed with conservative treatment, such as immobilization for a few weeks followed by gradual motion [3-5]. Groot et al. [6] reported two cases in patients with CTA and oral steroid therapy who had a scapular spine stress fracture managed by conservative treatment. Although good clinical outcomes were not obtained in another report, conserva-

Table 1. A review of literature
tive treatment seemed a reasonable alternative considering the risk of operative treatment in elderly patients [6]. On the other hand, several studies reported that acromial stress fractures in patients with CTA may need surgical treatment [5,7-9]. Karthik et al. [7] reported that fracture healing either by conservative or operative treatment is associated with a good functional outcome. Dennis et al. [5] reported four cases describing stress fracture of the anterior acromion associated with CTA. One patient had conservative treatment. Three cases had operative treatment, including two with fragment excision and one with total shoulder arthroplasty and fragment excision. They described the fracture site bathed in synovial fluid, which may make union less likely due to the associated rotator cuff tear [5]. They recommended surgical excision of the fragment rather than internal fixation, as the healing potential is thought to be poor. In previously reported cases, two patients with failed conservative treatment for scapular spine stress fracture underwent ORIF and experienced good clinical outcomes with fracture healing after surgery [7,9]. Considering the previously reported cases and our cases, we recommend initial conservative treatment in patients with stress fracture of the acromion or scapular spine. If conservative treatment fails, we recommend ORIF rather than fragment excision and rotator cuff repair, or RTSA may be not necessary.
